## ABSTRACT

Wheat is one of the most staple foods of the Nepalese diet which is grown in the winter season in most of the area of the country. The study was carried out during *winter* of the year 2019-2020 at College Agronomy Farm, B.A. College of Agriculture, Anand Agricultural University, Anand (Gujarat) to study the response of Integrated Nutrient Management in irrigated wheat under sandy loam soil. Experimental soil is low in organic carbon (0.39 %) and medium in available phosphorus (37.22 kg/ha) and potassium (247 kg/ha) with slightly alkaline (pH 7.85) in reaction. Application of 75% RDN + 25% N through neem cake + *Jeevamrut* (500 lit/ha) treatment reported significantly higher growth attributes and yield attributes like plant height at 30 (25.76 cm), 60 (71.84 cm) DAS and at harvest (119.64 cm), length of spike (10.35 cm), number of effective (305) and total tillers (351), no of grains per spike (49.62). Wheat grain (6389 kg/ha) and straw yield (8950 kg/ha) were significantly higher in 75% RDN + 25% N through neem cake + *Jeevamrut* (500 lit/ha). Crude protein content (13.75 %), soil organic carbon (0.48%) and available phosphorus (53.52 kg/ha) was higher by application of 75% RDN + 25% N through neem cake + *Jeevamrut* (500 lit/ha). Soil microbial population after second and third irrigation was found to be significant by application of 50% RDN + 25% N through neem cake + NP consortium + *Jeevamrut* (500 lit/ha), while after first irrigation response of treatment on soil microbial population, soil pH and EC were found non-significant (p=0.05).

## 1. INTRODUCTION

Wheat is a key staple food that provides around 20 percent of protein and calories consumed worldwide. Demand for wheat is projected to continue to grow over the coming decades, particularly in the developing world to feed an increasing population and with wheat being a preferred food, continuing to account for a substantial share of human energy needs in 2050.

Integrated nutrient management (INM) is a vital process, and it is the perfect combination of mineral fertilizer, organic manure, compost or bio-fertilizers, and the amalgamation of micronutrients [1]. Integrated nutrient management is practice where all the sources of nutrients namely organic, inorganic and bio-fertilizer as well as liquid organic manures can be combined and applied to soil so that crop growth is enhanced, and we can get good yield with quality product. Liquid organic manure, *jeevamrut* has the potential to play the role of promoting growth and providing resistance in the plant system. Descriptions of this holy combination could be traced to Vedas, the divine scripts of Indian wisdom. Application of *jeevamrut* in agriculture is a good option to supplement nutrient requirement of crops as it is easy to prepare, cost effective, easily available, more reliable and eco-friendlier.

*Jeevamrut* and *beejamrut* is a liquid organic manure popularly used as means of organic farming as well as integrated nutrient management system. It is excellent source of natural carbon, biomass, Nitrogen, Phosphorus, Potassium and lot of other forms of manure, compost and vermicompost. *Jeevamrut* established to be significant because it maintains the fertility of soil and helps in enhancement of growth and development of plants. *Jeevamrut* also comes in one of the low-cost formulations which are responsible for the enhancement of soil with indigenous micro-organisms required for better mineralization of soil and its helps in enhancement of growth of plant [2,3,4]. Present era is on integrated nutrient system and we have to observed all possible side with its benefit for successful crop production. View of these objects present studies on integrated nutrient management was taken and it included combined used organic manures, liquid fermented manures, chemical fertilizers and micro organized and its response on irrigated wheat.

## 2. MATERIALS AND MATHODS

A field experiment was conducted at College Agronomy Farm, B. A. College of Agriculture, Anand Agricultural University, Anand (Gujarat) during *winter* of the year 2019-20 to study the effect of integrated nutrient management in irrigated wheat. The soil of the experimental field was loamy sand in texture, medium in organic carbon (0.39 %) and medium in available phosphorus (37.22 kg/ha) and available potash (247 kg/ha) with slightly alkaline (pH 7.85) in reaction. Wheat variety Gujarat Wheat 451 (GW 451) was selected for experiment. The experiment was arranged in randomized block design with three replications, consisting of ten treatments **$T_1$**: 100% RDN through chemical fertilizer, **$T_2$:** 75% RDN + 25% N through neem cake, **$T_3$:** 75% RDN + 25% N through neem cake + NP consortium, **$T_4$:** 75% RDN + 25% N through neem cake + *Jeevamrut* (500 lit/ha), **$T_5$:** 50% RDN+ 50% N through neem cake, **$T_6$:** 50% RDN + 50% N through neem cake + NP consortium, **$T_7$:** 50% RDN + 50% N through neem cake + *Jeevamrut* (500 lit/ha), **$T_8$:** 50% RDN + 25% N through neem cake + NP consortium + *Jeevamrut* (500 lit/ha), **$T_9$:** 50% RDN + NP consortium + *Jeevamrut* (500 lit/ha), **$T_{10}$:** NP consortium + *Jeevamrut* (500 lit/ha). Recommended nitrogen (120 kg N/ha) was given in form of Urea at 50% as a basal and remaining 50% nitrogen in two splits at CRI (Crown root initiation) and tillering stage while recommended dose of phosphorus (60 kg $P_2O_5$/ha) in the form of Single Super Phosphate was applied as a basal. Application of bio NP consortium with seed treatment (5 ml/kg) and soil application (1 lit/ha) with first three irrigation as per treatments. Application of *jeevamrut* (500 lit/ha) at first three irrigation as per treatment. After sowing crops and proper germination in all plots, selected and tagged five random plant in net plot area for further growth and yield observations. The protein content of grain was assessed by multiplying nitrogen content of the seed (%) with the conversion factor of 6.25. Soil sample were collected after five days of irrigation applied for first three irrigation plot wise separately and stored in polythene bags and kept at $4^oC$ till processed. Microbial count done by serial dilution technique (Dhingra and Sinclair, 1993) and spreaded on nutrient agar (NA) plat and

incubated at 30-35$^{o}$ C for 2-3 days in incubator. Colonies were counted by using colonies counter meter and total microbial count were taken by following formula;

Final count (cfu/g) = (Number of well isolated colonies x Dilution factor / Aliquot taken)

The collected data for various parameters were statistically analysed using Fishers analysis of variance (ANOVA) technique and the treatments were compared at 5% levels of significance [5]. All the observation, growth and yield parameters were taken as per standard method.

## 3. RESULTS AND DISCUSSION

Response of different integrated nutrient management treatments on plant population in meter row length was found non-significant (p=0.05) at 20 DAS, it might be due to uniform germination in all treatments, at initial stage response of nutrient was found non-significant, so uniformity was observed. Application of 75 % RDN + 25 % N through neem cake + *Jeevamrut* (500 lit/ha) reported significantly (p=0.05) higher plant at 30, 60 DAS and at harvest (25.76,71.84 and 119.64 cm, respectively). Significantly (p=0.05) higher plant might be due to organic manure could be attributed to slow release of nitrogen and increased availability of micro and macro nutrients available in neem cake to produce new meristematic tissues. Besides, NPK and micronutrients are also available in neem cake which plays a vital role in various metabolic activities of plants and catalytic role in activating several enzymes [6, 7 and 8]. The liquid organic manures contain microbial population and plant growth promoting substances that help in improving plant growth, metabolic activities of plants.

Application of 75% RDN + 25% N through neem cake + *Jeevamrut* (500 lit/ha) reported significantly higher length of spike (10.35 cm), effective and total tillers per meter row length (305 and 351, respectively), number of spikes per plant at harvest (10.40) and number of grains per spikes (49.62) but it did not differ significantly (p=0.05) with treatment $T_1$ (100% RDN through chemical fertilizer). Response on growth attributing characters might be due to combined effect of organic manure, biofertilizers and chemical fertilizers in balanced proportion played a very important role in decomposition and easy release of different nutrients and their uptake by the crop which result into higher dry matter accumulation and its translocation in different plant parts of growth and yield parameters, which resulted into higher yield. *Jeevamrut* content major and micronutrient which are rapidly available and easily absorbed and helps in faster growth and development of plant component. Similar line of results was also reported by [9, 10, and 11] (Fig.02).

Data presented in Fig.03 revealed that significantly (p=0.05) higher grain yield (6389 kg/ha) and straw yield (8950 kg/ha) was observed significantly higher in $T_4$ (75% RDN + 25% N through neem cake + *Jeevamrut* (500 lit/ha) treatment. Treatment $T_4$ (75% RDN + 25% N through neem cake + *Jeevamrut* (500 lit/ha) reported 6.16% higher grain yield over 100 % RDF treatment ($T_1$). Significantly higher grain and straw yield by application of organic and inorganic nutrients might be due to supply of balanced amount of essential nutrients to plants in suitable proportion and forms. It is well established fact that the incorporation of organic manure not only acts as a store house of major and micronutrients but is also influence the physical, chemical and biological properties of soil [12]. Organic manure contains almost all the essential plant nutrients, its incorporation in soil in conjunction with inorganic fertilizers promotes rapid vegetative growth and tillering, thereby, increasing the sink size in terms of ear and grain growth. The application liquid manure supplied the required metabolites to the source and further greater accumulation of assimilates in the sink [11, 13] reported that *jeevamrut* can release the nutrients in a more synchronized manner as per the need of the crops and *jeevamrut* enhances microbial activity in soil and helps in mobilization of nutrient in soil. Other reason might be due to combined effect of organic manure (FYM), biofertilizers and chemical fertilizers with sulphur in balanced proportion played a very vital role in decomposition and easy release of different nutrients and their uptake by the crop which led to higher dry matter accumulation and its translocation in different plant parts of growth and yield parameters, which in turn resulted into higher yield [9].

Protein content (13.75 %) was found to be significantly (p=0.05) higher in treatment $T_4$ (75% RDN + 25% N through neem cake + *Jeevamrut* (500 lit/ha) than rest of integrated nutrient management treatments except treatment $T_1$ (100% RDN through chemical fertilizer). The response of treatment on soil pH and EC did not differ significantly (p=0.05) by effect of various

| $T_8$ | 11.60 | 108.44 | 148.44 | 173.44 | 8.00 | 0.25 | 0.45 | 43.62 |
| $T_9$ | 9.29 | 107.88 | 147.88 | 172.88 | 8.03 | 0.27 | 0.39 | 38.99 |
| $T_{10}$ | 9.12 | 95.2 | 138.54 | 163.54 | 7.99 | 0.27 | 0.38 | 37.51 |
| S. Em. ± | **0.57** | **6.23** | **6.78** | **7.29** | **0.26** | **0.01** | **0.02** | **1.86** |
| CD(P=0.05) | **1.69** | **NS** | **20.13** | **21.66** | **NS** | **NS** | **0.05** | **5.54** |
| CV % | 8.76 | 11.12 | 8.61 | 7.91 | 5.61 | 8.85 | 6.51 | 7.32 |

treatments. Application of 75% RDN + 25% N through neem cake + *Jeevamrut* (500 lit/ha ($T_4$) reported higher organic carbon (0.48 %) and available $P_2O_5$ (53.52 kg/ha). Soil microbial population was found non-significant (p=0.05) at first irrigation, but it was significantly (p=0.05) higher during second (148.44×106 cfu/g) and third irrigation (173.44 × 106 cfu/g) under treatment 50% RDN + 25% N through neem cake + NP consortium + Jeevamrut (500 lit/ha). Increasing microbial population might be due to availability of abundant organic matter and effective microbial activities because of sufficient supply of feeding material for microorganism in the form of humus. Similar finding reported by Pawar et al. [14].

## 4. ECONOMICS

Based on present market prices of wheat seed and straw as well as different variable and non-variable inputs. The data on cost of cultivation, gross and net return as well as BCR were calculated for different treatments are presented in Fig.04. Application of treatment $T_1$ (100% RDN through chemical fertilizer) recorded higher net

realization (Rs. 95907/ha) and BCR value (4.6) followed by application of treatment $T_4$ [75% RDN + 25% N through neem cake + *Jeevamrut* (500 lit/ha)] recorded net realization (Rs.82677/ha) and BCR value (2.76). However, lower net realization and BCR value recorded under application of treatment $T_5$ (50% RDN+ 50% N through neem cake).

## 4. CONCLUSION

Based on the above results, it can be concluded that the grain yield and economics of wheat can be improved by using different integrated nutrient management treatment. Experiment results also revealed that wheat morphological and physiological parameters improved by application of organic and inorganic with liquid manure.
